Dar triad is a popular theory all about the dark side of your personality. The theory was proposed by two researchers Delroy L. Paulhus and Kevin M. Williams in 2002 in a research journal. The theory focuses on the dark side of the personality and these two researchers believe that every person has a dark side of personality to some extent. Some people might have a high level of dominance and others might have a low.

This theory led to the development of self-assessment tools and here we will discuss whether these tools are valid or not.

First, we might keep in mind that self-assessment reports are not perfect and definitive tools for measuring personality traits but can be predicted by scoring the responses given by the participants.

We have tried the official dark triad test which is 27 27-item test and another one is a sort which consists of 12 questions. We also included Deenz 33-item dark triad scale

In our findings, we found that participants hesitated to answer the items because of privacy concerns so we asked participants not to enter names and any other personal information.

Results:

In our research, we found that the test results were accurate based on the feedback from the participants. The SDT was rated 3.⅘ and Deenz dark triad personality scale has been rated 4.8/5. Thus Deenz dark triad personality scale produced accurate results as it was mixed with the negative as well as positive items which minimized the risk of faking.

Final Thoughts

In the field of psychology, self-assessments play a vital role in studying human behavior but every person is unique and we can't measure the personality just by a tool.
